Homework 1 (Sept. 20)

Deadline: Wednesday, October 4th, at 11:59pm.

Submission: You need to submit separate PDF files to each question via Crowdmark. For Question 5, your submission should also contain the <u>R code</u> and <u>R outputs</u>. You can produce the PDF's however you like (e.g. LATEX, Microsoft Word, scanner), as long as they are legible.

Neatness Point: You will be deducted one point if we have a hard time reading your solutions or understanding the structure of your code.

Late Submission: 10% of the total possible marks will be deducted for each day late, up to a maximum of 3 days. After that, no submissions will be accepted.

• **Problem 1 (4 pts)** (This problem is to show you that why f is the best predictor of Y under the mean squared loss.)

Assume that we have the regression model

$$Y = f(X) + \epsilon$$

where ϵ is independent of X and $\mathbb{E}[\epsilon] = 0$, $\mathbb{E}[\epsilon^2] = \sigma^2$.

1. (2 pt) Prove that

$$f(X) = \mathbb{E}[Y \mid X].$$

2. (2 pts) Prove that

$$\mathbb{E}[Y \mid X] = \operatorname*{argmin}_{g} \mathbb{E}\Big[(Y - g(X))^2 \Big].$$

Hint: we have the fact that $\mathbb{E}[h(X,Y)] = \mathbb{E}_X \mathbb{E}_{Y|X}[h(X,Y) \mid X]$.

SOLUTION:

1. Proof.

$$\begin{split} \mathbb{E}[Y\mid X] &= \mathbb{E}[f(X)\mid X] + \mathbb{E}[\epsilon\mid X] \\ &= f(X) + \mathbb{E}[\epsilon] & X \text{ is independent of } \epsilon \\ &= f(X) & \mathbb{E}[\epsilon] = 0. \end{split}$$

2. **Proof.** For any function g, we have

$$\begin{split} \mathbb{E}\Big[(Y-g(X))^2\Big] &= \mathbb{E}_X \mathbb{E}_{Y|X}\Big[(Y-g(X))^2 \mid X\Big] \\ &= \mathbb{E}_X\Big[\mathbb{E}[Y^2 \mid X] - 2g(X)\mathbb{E}[Y \mid X] + (g(X))^2\Big] \\ &= \mathbb{E}_X\Big[(\mathbb{E}[Y \mid X])^2 + \mathrm{Var}(Y \mid X) - 2g(X)\mathbb{E}[Y \mid X] + (g(X))^2\Big] \\ &= \mathbb{E}_X\Big[(\mathbb{E}[Y \mid X] - g(X))^2\Big] + \mathbb{E}_X[\mathrm{Var}(Y \mid X)]. \end{split}$$

Since the second term is independent of g(X), the minimizer is $\mathbb{E}[Y \mid X]$.

• **Problem 2 (6 pts)** (You will derive the Bias-Variance-Tradeoff formula in the lecture.) Assume that we have the regression model

$$Y = f(X) + \epsilon,$$

where ϵ is independent of X and $\mathbb{E}(\epsilon) = 0$, $\mathbb{E}(\epsilon^2) = \sigma^2$. Assume that the training data $(x_1, y_1), ..., (x_n, y_n)$ are used to construct an estimate of f, denoted by \hat{f} . Given a new random vector (X, Y) (independent of the training data),

1. **(3 pts)** show that

$$\mathbb{E}\left[(f(x) - \hat{f}(x))^2 \mid X = x\right] = \operatorname{Var}\left(\hat{f}(x)\right) + \left[\mathbb{E}[\hat{f}(x)] - f(x)\right]^2. \tag{0.1}$$

Hint: You may benefit from adding and subtracting terms, such as

$$f(x) - \hat{f}(x) = f(x) - \mathbb{E}[\hat{f}(x)] + \mathbb{E}[\hat{f}(x)] - \hat{f}(x)$$

2. **(3 pts)** show that

$$\mathbb{E}\left[\left(Y - \hat{f}(x)\right)^2 \mid X = x\right] = \operatorname{Var}\left(\hat{f}(x)\right) + \left(\mathbb{E}[\hat{f}(x)] - f(x)\right)^2 + \sigma^2.$$

SOLUTION:

1. **Proof.** Since X is independent of \hat{f} , we have

$$\begin{split} &\mathbb{E}\Big[(f(x)-\hat{f}(x))^2\mid X=x\Big]\\ &=\mathbb{E}\Big[(f(x)-\hat{f}(x))^2\Big]\\ &=\mathbb{E}\Big[\Big(f(x)-\mathbb{E}[\hat{f}(x)]+\mathbb{E}[\hat{f}(x)]-\hat{f}(x)\Big)^2\Big]\\ &=\mathbb{E}\Big[\Big(f(x)-\mathbb{E}[\hat{f}(x)]\Big)^2\Big]+\mathbb{E}\Big[\Big(\mathbb{E}[\hat{f}(x)]-\hat{f}(x)\Big)^2\Big]\\ &+2\mathbb{E}\Big[\Big(f(x)-\mathbb{E}[\hat{f}(x)]\Big)\Big(\mathbb{E}[\hat{f}(x)]-\hat{f}(x)\Big)\Big]\\ &=\Big(f(x)-\mathbb{E}[\hat{f}(x)]\Big)^2+\mathrm{Var}\Big(\hat{f}(x)\Big)+2\Big(f(x)-\mathbb{E}[\hat{f}(x)]\Big)\Big(\mathbb{E}[\hat{f}(x)]-\mathbb{E}[\hat{f}(x)]\Big)\\ &=\Big(f(x)-\mathbb{E}[\hat{f}(x)]\Big)^2+\mathrm{Var}\Big(\hat{f}(x)\Big) \end{split}$$

as desired.

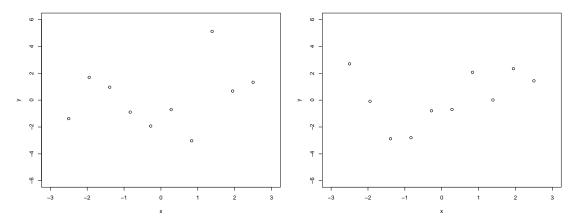

2. Proof.

$$\begin{split} & \mathbb{E}\left[\left(Y - \hat{f}(x)\right)^{2} \mid X = x\right] \\ & = \mathbb{E}\left[\left(f(x) - \hat{f}(x)\right)^{2} \mid X = x\right] + \mathbb{E}\left[\epsilon^{2} \mid X = x\right] + \mathbb{E}\left[\epsilon\left(f(x) - \hat{f}(x)\right) \mid X = x\right] \\ & = \mathbb{E}\left[\left(f(x) - \hat{f}(x)\right)^{2} \mid X = x\right] + \mathbb{E}\left[\epsilon^{2} \mid X = x\right] + \mathbb{E}\left[\epsilon \mid X = x\right] \cdot \mathbb{E}\left[f(x) - \hat{f}(x) \mid X = x\right] \\ & = \mathbb{E}\left[\left(f(x) - \hat{f}(x)\right)^{2} \mid X = x\right] + \mathbb{E}\left[\epsilon^{2}\right] + \mathbb{E}\left[\epsilon\right] \cdot \mathbb{E}\left[f(x) - \hat{f}(x) \mid X = x\right] \\ & = \mathbb{E}\left[\left(f(x) - \hat{f}(x)\right)^{2} \mid X = x\right] + \sigma^{2} \end{split}$$

where the penultimate step uses the independence between ϵ and \hat{f} while the last step uses the independence between ϵ and X. The result follows by using part (1).

• Problem 3 (6 pts)

Suppose we have observed the following data points $(x_i, y_i)_{1 \le i \le 10}$ shown in the left panel. Further suppose we have observed a different set of data points generated from the same model (see, the right panel). Answer the following questions.

- (1 pt) Draw on both pictures what a fitted linear predictor (trained by using each data set) looks like (use the dotted line type or red).
- (1 pt) Draw on both pictures what an overfitted predictor (trained by using each data set) looks like (use the solid line type or black).
- (2 pts) For both the linear predictor and the overfitted predictor that you drew, state their predicted values for x = 1.5. (e.g. you should have two values for each type of predictor trained by using each data set)
- (2 pts) Comment on the predicted values in the previous part as well as the variances
 of these two types of predictors.

SOLUTION:

- For linear predictors, they should be two linear lines. As long as the fitted lines are reasonable, we can grant full credits.
- It should represent the overfitted patterns, including interpolation.
- Should match with the fitted lines they provide in the above two parts.
- They should be able to deduce that the variance of the linear predictor is smaller than that of the overfitted one.

• Problem 4 (8 pts)

For each of parts (a) through (d), indicate whether we would generally expect the performance of a flexible statistical learning method to be better or worse than an inflexible method. Justify your answer.

- (a) (2 pts) The sample size n is extremely large, and the number of predictors p is small.
- (b) (2 pts) The number of predictors p is extremely large, and the number of observations n is small.
- (c) (2 pts) The variance of the error terms, i.e. $\sigma^2 = \text{Var}(\epsilon)$, is extremely high.
- (d) (2 pts) The relationship between the predictors and response is highly non-linear.

SOLUTION:

- 1. The performance of a flexible statistical learning method would be better than an inflexible one. From the bias-variance trade off formula, when we have extremely large n, then the variance term for any model will be closed to zero hence the bias term will dominate. A flexible method will have much smaller bias than an inflexible one since it can approximate any distribution.
- 2. The performance of a flexible statistical learning method would be worse, since it will probably overfit.
- 3. If the variance of the noise is extremely large, then both flexible methods and inflexible methods will have bad performance. However, a flexible method is possible to be worse. It will have a risk of overfitting and the model mainly captures the errors in the data. An inflexible method will be more robust to the noise.
- 4. The performance of a flexible statistical learning method would be better. The flexible method can approximate non-linear dependency between the predictors and response better than an inflexible method such as linear regressions.

• Problem 5 (16 pts)

This question should be answered using the Carseats data set which is contained in the R package ISLR. Each sub-question is worth 2 pts.

- (a) Fit a multiple regression model to predict Sales using Price, Urban, and US.
- (b) Provide an interpretation of each coefficient in the model. Be careful—some of the variables in the model are qualitative!
- (c) Write out the model in equation form, being careful to handle the qualitative variables properly.
- (d) For which of the predictors can you reject the null hypothesis $H_0: \beta_j = 0$? Use the significance level 0.05 for the hypothesis test.
- (e) On the basis of your response to question (d), fit a smaller model that only uses the predictors for which there is evidence of association with the outcome.
- (f) What are the value of \mathbb{R}^2 for models in (a) and (e)? Does larger \mathbb{R}^2 mean the model fit the data better?
- (g) Using the model from (e), construct the 95 % confidence interval(s) for the coefficient(s).
- (h) Fit a linear regression model in (e) with interaction effect(s). Provide an interpretation of each coefficient in the model.

SOLUTION: See the HW1Q5.pdf.
